Notes on Parameters for Hyperparameter Optimization in Machine Learning

Luis Mendez

Parameters in ML models

The objective of a typical learning algoritm is to find a function f that maps input data X to output labels Y. The function f is defined by a set of parameters θ, which are learned from the training data. For example, in a linear regression model, the parameters are the coefficients of the linear equation. In a neural network, the parameters are the weights and biases of the network. The learning algorithm adjusts these parameters to minimize a loss function, which measures the difference between the predicted output and the true output.

The coefficients of the linear function, are the parameters to find or optimise by the algortihm. The learning algorithm adjusts these parameters to minimize a loss function, which measures the difference between the predicted output and the true output.
